(57) A method and an apparatus whereby the information appearing on a CRT screen is separately displayed in braille, using a braille web 100 in a loop form which is made partly or wholly from a shape memory resin. The information from a CRT screen 410 is input to the web 100 by a braille printer 300 in a temperature range below the glass transition temperature of the resin. After the information has

been read by the user, the displayed web portion is heated above the glass transition temperature by a heating roller 200 so that the web recovers its original, non-braille shape. The restituted web is conveyed by a driving roller 210 along with the heating roller 200 and a driven roller 220 in the directions indicated by arrows in Fig. 1 for repeated use.

EP 0 525 922 A2

FIG. 1

FIELD OF THE INVENTION AND RELATED ART STATEMENT

The present invention relates to a method and an apparatus for separately displaying in braille the information appearing on a cathode-ray-tube (CRT) screen, using a shape memory resin as a display medium.

For the purposes of the invention the term "braille" is intended not merely to mean the braille in a limited sense but to encompass all other representations of characters, symbols, and patterns in tangible forms for reading by touch. By a "braille web" is meant any web or web-like layer for recording the braille. The expression "recovery of the braille web" is used to mean correcting or erasing part or whole of the braille and allowing the web to recover its original, non-brailled shape.

In order that a visually handicapped person may have an access to the information displayed on a CRT screen, it has been necessary to transcribe the information in braille or pin display characters that can be read via the fingertips. Braille is a system of writing texts as combinations of tangible symbols so devised that the visually handicapped person can read them by touch. The symbols are represented each by a plurality of raised dots in a cell formed on a braille paper made chiefly of pulp fiber.

A pin display is a device for projecting from a plate surface a plurality of pins in suitable combinations in the same arrangement as in braille. Transcription of the information appearing on a CRT screen into braille or pin display characters is a two-step practice, first forming braille codes from the text information using a character/braille conversion software and then driving a braille printer or pin display for printing on braille paper or for pin displaying.

Conventional methods of transcribing the information from a CRT screen into braille or pin displaying have the following drawbacks.

When printing with a braille printer, the braille paper must be replaced by a new, blank sheet each time the display on the CRT screen is shifted from scene to scene. Once printed, the ordinary braille paper cannot be reused, and this adds greatly to the cost of braille displaying of the information from a CRT that handles an enormous volume of data. Pin display, on the other hand, is a device only suited for displaying an amount of information enough for about one line at a time. It takes an unduly long period of time to display a CRT screenful of information. Rebuilding the device to display the whole-screen information would make the construction so complex that the manufacture and maintenance would involve too much difficulties for the realization of the scheme.

OBJECT AND SUMMARY OF THE INVENTION

The present invention, made in view of the foregoing, is aimed at providing a method and an apparatus for braille display of information appearing on a CRT screen, using a braille web made of a shape memory resin which permits the recorded braille characters to be easily erased and allows the web to recover its original shape or non-recorded state for repetitive use.

The above aim is achieved by a method of the invention for braille display of information appearing on a CRT screen, which comprises converting the information into braille information, printing the braille information on a braille web of a shape memory resin by a braille printer, conveying the braille web in succession to a display window so that the user can read it, subsequently heating at least the printed area of the braille web to a temperature above the glass transition temperature of the shape memory resin so as to erase the recorded information and to restore the original, non-recorded state of the web, and repeating the afore-said steps, whereby the information on the CRT screen can be continuously displayed in braille.

The above aim is also achieved by an apparatus of the invention for braille display of information appearing on a CRT screen, comprising a CRT display, a converter for converting the information on the CRT screen into braille information, a braille printer for printing the braille information from the converter on a braille web, braille web feeder means for continuously feeding the braille web formed from a shape memory resin to the braille printer, a display window disposed downstream of the braille printer to provide the user with an access to the braille information transcribed on the braille web, and a heater located further downstream of the display window to heat at least the printed area of the braille web.

A shape memory resin markedly changes its modulus of elasticity below and above its glass transition region or a temperature range including its glass transition temperature T_g . It is deformed with permanent strain when subjected to an external force at a temperature below the glass transition temperature T_g . The permanent strain, however, disappears when the resin is heated above the glass transition temperature T_g . Thus the shape memory resin, after being deformed, can recover its original shape on heating to a temperature above its glass transition temperature T_g .

When a material consisting partly or wholly of such a shape memory resin is formed into a sheet or web at a temperature below the glass transition temperature T_g and is employed in place of the existing braille paper, it is possible to record in braille the information, including patterns, that ap-

appears on a CRT screen at room temperature which is lower than the glass transition temperature T_g . Since the permanent strain that has resulted from the braille recording can be eliminated upon heating above the glass transition temperature T_g , the braille web recovers its original shape. Consequently, the braille web can be used repeatedly, and the apparatus for the braille display of CRT-screen information can be simplified in construction, and related costs are reduced.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a perspective view of the first embodiment of the CRT information-braille display apparatus according to the present invention;

Fig. 2 is a cross-sectional view of the essential parts of the first embodiment of the invention;

Figs. 3(A) and 3(B) are side views illustrating the construction of the printing section in the above embodiment; and

Fig. 4 is a cross-sectional view of the essential parts of the second embodiment of the invention.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

An embodiment of the present invention will now be described in detail with reference to the accompanying drawings.

Figure 1 shows, in perspective, the first embodiment of the CRT-information braille display apparatus of the invention, and Fig. 2 shows, in cross section, the essential parts of the embodiment. In these figures, a braille web 100 in loop form is made partly or wholly of a shape memory resin. It is driven endlessly by means of a heating roller 200, driving roller 210, or driven roller 220 in the directions indicated by the arrows in the figures.

Information from a CRT screen 410 is transmitted through a cord 510 to a character-pattern/braille converter 400, where it is converted to braille information. The latter then is sent via a cord 500 to a braille printer 300. The braille printer 300 prints the inputted braille characters or graphical patterns onto the braille web 100 in a temperature region below the glass transition temperature. As Fig. 3(a) shows, the printing is carried out as a needle 330 moves reciprocatingly up and down and left to right. An upper presser plate 310 is located on the side of the braille web opposite to the needle 330 to provide protection for the web and ensure clear impression of the braille characters. The presser plate 310 is formed with grooves 311 as shown in Fig. 3(b) to protect the braille information from being marred by scratching or catching of the braille web 100 while being fed.

The information 120 printed on the braille web 100 is conveyed to a display window 110 which is large enough to represent the whole data from the CRT screen 410 and allow the user ready access to the tangible information for reading. As indicated in Fig. 2, the display window 110 is protected with an outer frame 420 secured partly or wholly to the housing of the braille display apparatus so as to keep the user's hand off from the braille printer 300 or the heating roller 200. The window 110 is also protectively supported from below by an under plate 320 lest the braille web 100 be elongated by the fingertips that come in touch.

The braille web 100 is driven from the display window 110 to the heating roller 200, where it is heated above the glass transition temperature to recover its original, non-brailled shape. The recovered braille web is moved farther by the heating roller 200, driving roller 210, and free roller 220 in the direction indicated by the arrows in Fig. 1 for repeated use.

Another embodiment of the CRT-information braille display apparatus according to the invention is shown in Fig. 4 as a cross-sectional view of its essential parts. Here the braille web 100 is not in loop form but is wound up in a roll on a feed roller 250. The braille web 100 unwound from the feed roller 250 is printed by a braille printer 300 and moved to a display window 110 for reading by the user. Next, the information transliterated in braille is erased by the heating roller 200 and the web restores its original, non-brailled state. The web then is pulled by a roller 230 and rewound by a take-up roller 240 for recovery.

The recovered roll of braille web 100 is set again on the feed roller 250 for repeated service. As a further alternative, this embodiment may dispense with the heating roller 200 so that, without the application of heat, the information transcribed on any desired web area can be stored unerased.

As has been described concretely in connection with the embodiments of the present invention, the use of a braille web consisting wholly or partly of a shape memory resin permits the restoration of the pre-brailled state of the web by heating above the glass transition temperature after the brailled information from a CRT screen has been read. Hence the advantage of continuously displaying the information from the CRT screen on a limited quantity of braille web.

Claims

1. A method for displaying in braille of information appearing on a CRT screen, which comprises converting information appearing on a CRT screen into braille information, printing the braille information on a braille web of a

shape memory resin by a braille printer, conveying the braille web in succession to a display window so that a user can read the printed braille information, subsequently heating at least a printed area of the braille web to a temperature above the glass transition temperature of the shape memory resin so as to erase the information recorded on the braille web and restore the original, non-recorded state of the web, and repeating the afore-said steps, whereby the information on the CRT screen can be continuously displayed in braille.

2. An apparatus for displaying in braille of information appearing on a CRT screen, comprising a CRT display, a converter for converting information on the CRT screen into braille information, a braille printer for printing the braille information from the converter on a braille web, braille web feeder means for continuously feeding the braille web formed from a shape memory resin to the braille printer, a display window disposed downstream of the braille printer so as to provide a user with an access to the braille information transcribed on the braille web, and a heater located further downstream of the display window for heating at least a printed area of the braille web.
3. The braille display apparatus as claimed in claim 2 wherein said braille web is in the form of a loop extending around braille web feeder means comprising a plurality of rollers inclusive of a driving roller.
4. The braille display apparatus as claimed in claim 3 wherein one said rollers is located downstream of said display window and is a heating roller serving as said heater.
5. The braille display apparatus as claimed in claim 2 wherein said braille web is wound in the form of a roll which is set on a feed roller for unrolling and a take-up roller is provided to rewind the unrolled web.

D scripti n

FIELD OF THE INVENTION AND RELATED ART STATEMENT

The present invention relates to a method and an apparatus for separately displaying in braille the information appearing on a cathode-ray-tube (CRT) screen, using a shape memory resin as a display medium.

For the purposes of the invention the term "braille" is intended not merely to mean the braille in a limited sense but to encompass all other representations of characters, symbols, and patterns in tangible forms for reading by touch. By a "braille web" is meant any web or web-like layer for recording the braille. The expression "recovery of the braille web" is used to mean correcting or erasing part or whole of the braille and allowing the web to recover its original, non-brailled shape.

In order that a visually handicapped person may have an access to the information displayed on a CRT screen, it has been necessary to transcribe the information in braille or pin display characters that can be read via the fingertips. Braille is a system of writing texts as combinations of tangible symbols so devised that the visually handicapped person can read them by touch. The symbols are represented each by a plurality of raised dots in a cell formed on a braille paper made chiefly of pulp fiber.

A pin display is a device for projecting from a plate surface a plurality of pins in suitable combinations in the same arrangement as in braille. Transcription of the information appearing on a CRT screen into braille or pin display characters is a two-step practice, first forming braille codes from the text information using a character/braille conversion software and then driving a braille printer or pin display for printing on braille paper or for pin displaying.

Conventional methods of transcribing the information from a CRT screen into braille or pin displaying have the following drawbacks.

When printing with a braille printer, the braille paper must be replaced by a new, blank sheet each time the display on the CRT screen is shifted from scene to scene. Once printed, the ordinary braille paper cannot be reused, and this adds greatly to the cost of braille displaying of the information from a CRT that handles an enormous volume of data. Pin display, on the other hand, is a device only suited for displaying an amount of information enough for about one line at a time. It takes an unduly long period of time to display a CRT screenful of information. Rebuilding the device to display the whole-screen information would make the construction so complex that the manufacture and maintenance would involve too much difficulties for the realization of the scheme.

The closest prior art is represented by the document JP-A-2-134 674. This document discloses:

A method for displaying in braille of information ap-

pearing on a CRT screen, which comprises converting information appearing on a CRT screen into braille information, forming the braille information on a braille web of a shape memory resin by heating heads, conveying the braille web in succession to a display window so that a user can read the formed braille information, subsequently applying pressure to at least a printed area of the braille web so as to erase the information recorded on the braille web and restore the non-recorded state of the web, and repeating the afore-said steps, whereby the information on the CRT screen can be continuously displayed in braille.

An apparatus for displaying in braille of information appearing on a CRT screen, comprising a CRT display, a converter for converting information on the CRT screen into braille information, heating heads for forming the braille information from the converter on a braille web, braille web feeder means for continuously feeding the braille web formed from a shape memory resin to the heating heads, a display window disposed downstream of the heating heads so as to provide a user with an access to the braille information transcribed on the braille web, and erasure rollers located further downstream of the display window for applying pressure to at least a printed area of the braille web.

OBJECT AND SUMMARY OF THE INVENTION

The present invention, made in view of the foregoing, is aimed at providing a method and an apparatus for braille display of information appearing on a CRT screen, using a braille web made of a shape memory resin which permits the recorded braille characters to be easily erased and allows the web to recover its original shape or non-recorded state for repetitive use.

The above aim is achieved by a method of the invention for braille display of information appearing on a CRT screen, which comprises converting the information into braille information, printing the braille information on a braille web of a shape memory resin by a braille printer, conveying the braille web in succession to a display window so that the user can read it, subsequently heating at least the printed area of the braille web to a temperature above the glass transition temperature of the shape memory resin so as to erase the recorded information and to restore the original, non-recorded state of the web, and repeating the afore-said steps, whereby the information on the CRT screen can be continuously displayed in braille.

The above aim is also achieved by an apparatus of the invention for braille display of information appearing on a CRT screen, comprising a CRT display, a converter for converting the information on the CRT screen into braille information, a braille printer for printing the braille information from the converter on a braille web, braille web feeder means for continuously feeding the braille web formed from a shape memory resin to the braille printer, a display window disposed downstream of the

braille printer to provide the user with an access to the braille information transcribed on the braille web, and a heater located further downstream of the display window to heat at least the printed area of the braille web.

A shape memory resin markedly changes its modulus of elasticity below and above its glass transition region or a temperature range including its glass transition temperature T_g . It is deformed with permanent strain when subjected to an external force at a temperature below the glass transition temperature T_g . The permanent strain, however, disappears when the resin is heated above the glass transition temperature T_g . Thus the shape memory resin, after being deformed, can recover its original shape on heating to a temperature above its glass transition temperature T_g .

When a material consisting partly or wholly of such a shape memory resin is formed into a sheet or web at a temperature below the glass transition temperature T_g and is employed in place of the existing braille paper, it is possible to record in braille the information, including patterns, that appears on a CRT screen at room temperature which is lower than the glass transition temperature T_g .

Since the permanent strain that has resulted from the braille recording can be eliminated upon heating above the glass transition temperature T_g , the braille web recovers its original shape. Consequently, the braille web can be used repeatedly, and the apparatus for the braille display of CRT-screen information can be simplified in construction, and related costs are reduced.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a perspective view of the first embodiment of the CRT information-braille display apparatus according to the present invention;

Fig. 2 is a cross-sectional view of the essential parts of the first embodiment of the invention;

Figs. 3(A) and 3(B) are side views illustrating the construction of the printing section in the above embodiment; and

Fig. 4 is a cross-sectional view of the essential parts of the second embodiment of the invention.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

An embodiment of the present invention will now be described in detail with reference to the accompanying drawings.

Figure 1 shows, in perspective, the first embodiment of the CRT-information braille display apparatus of the invention, and Fig. 2 shows, in cross section, the essential parts of the embodiment. In these figures, a braille web 100 in loop form is made partly or wholly of a shape memory resin. It is driven endlessly by means of a heating roller 200, driving roller 210, or driven roller 220 in the directions indicated by the arrows in the fig-

ures.

Information from a CRT screen 410 is transmitted through a cord 510 to a character-pattern/braille converter 400, where it is converted to braille information. The latter then is sent via a cord 500 to a braille printer 300. The braille printer 300 prints the inputted braille characters or graphical patterns onto the braille web 100 in a temperature region below the glass transition temperature. As Fig. 3(a) shows, the printing is carried out as a needle 330 moves reciprocatingly up and down and left to right. An upper presser plate 310 is located on the side of the braille web opposite to the needle 330 to provide protection for the web and ensure clear impression of the braille characters. The presser plate 310 is formed with grooves 311 as shown in Fig. 3(b) to protect the braille information from being marred by scratching or catching of the braille web 100 while being fed.

The information 120 printed on the braille web 100 is conveyed to a display window 110 which is large enough to represent the whole data from the CRT screen 410 and allow the user ready access to the tangible information for reading. As indicated in Fig. 2, the display window 110 is protected with an outer frame 420 secured partly or wholly to the housing of the braille display apparatus so as to keep the user's hand off from the braille printer 300 or the heating roller 200. The window 110 is also protectively supported from below by an under plate 320 lest the braille web 100 be elongated by the fingertips that come in touch.

The braille web 100 is driven from the display window 110 to the heating roller 200, where it is heated above the glass transition temperature to recover its original, non-brailled shape. The recovered braille web is moved farther by the heating roller 200, driving roller 210, and free roller 220 in the direction indicated by the arrows in Fig. 1 for repeated use.

Another embodiment of the CRT-information braille display apparatus according to the invention is shown in Fig. 4 as a cross-sectional view of its essential parts. Here the braille web 100 is not in loop form but is wound up in a roll on a feed roller 250. The braille web 100 unwound from the feed roller 250 is printed by a braille printer 300 and moved to a display window 110 for reading by the user. Next, the information transliterated in braille is erased by the heating roller 200 and the web restores its original, non-brailled state. The web then is pulled by a roller 230 and rewound by a take-up roller 240 for recovery.

The recovered roll of braille web 100 is set again on the feed roller 250 for repeated service. As a further alternative, this embodiment may dispense with the heating roller 200 so that, without the application of heat, the information transcribed on any desired web area can be stored unerased.

As has been described concretely in connection with the embodiments of the present invention, the use of a braille web consisting wholly or partly of a shape memory resin permits the restoration of the pre-brailled

state of the web by heating above the glass transition temperature after the brailled information from a CRT screen has been read. Hence the advantage of continuously displaying the information from the CRT screen on a limited quantity of braille web.

Claims

1. A method for displaying in braille of information appearing on a CRT screen (410), which comprises converting information appearing on a CRT screen (410) into braille information, printing the braille information on a braille web (100) of a shape memory resin by a braille printer (300), conveying the braille web in succession to a display window (110) so that a user can read the printed braille information, subsequently heating at least a printed area of the braille web to a temperature above the glass transition temperature of the shape memory resin so as to erase the information recorded on the braille web and restore the original, non-recorded state of the web, and repeating the afore-said steps, whereby the information on the CRT screen (410) can be continuously displayed in braille.
2. An apparatus for displaying in braille of information appearing on a CRT screen, comprising a CRT display (410), a converter (400) for converting information on the CRT screen (410) into braille information, a braille printer (300) for printing the braille information from the converter (400) on a braille web (100), braille web feeder means (200, 210, 220) for continuously feeding the braille web (100) formed from a shape memory resin to the braille printer (300), a display window (110) disposed downstream of the braille printer (300) so as to provide a user with an access to the braille information transcribed on the braille web (100), and a heater (200) located further downstream of the display window (110) for heating at least a printed area of the braille web (100).
3. The braille display apparatus as claimed in claim 2 wherein said braille web (100) is in the form of a loop extending around braille web feeder means (200, 210, 220) comprising a plurality of rollers inclusive of a driving roller (210).
4. The braille display apparatus as claimed in claim 3 wherein one said rollers is located downstream of said display window and is a heating roller (200) serving as said heater.
5. The braille display apparatus as claimed in claim 2 wherein said braille web (100) is wound in the form of a roll which is set on a feed roller for unrolling and a take-up roller is provided to rewind the unrolled

web.

Patentansprüche

1. Verfahren zur Ausgabe von Informationen eines Bildschirms (410) in Blindenschrift, das die Umkodierung der auf einem Bildschirm (410) angezeigten Informationen in blindenschriftkodierte Informationen, das Prägen der blindenschriftkodierten Informationen auf einer Blindenschriftträgerbahn (100) aus einem rückverformbaren Kunststoff mit Hilfe einer Blindenschriftprägemaschine (300), den anschließenden Transport der Blindenschriftträgerbahn zu einem Ausgabefenster (110), so daß ein Leser die in Blindenschrift geprägten Informationen lesen kann, danach das Erhitzen mindestens eines Abschnitts der geprägten Blindenschriftträgerbahn auf eine Temperatur oberhalb der Glasübergangstemperatur der Blindenschriftträgerbahn zum Löschen der auf der Blindenschriftträgerbahn aufgetragenen Informationen, die Rückführung dieser in den Ausgangszustand ohne Blindenschrift und die Wiederholung der vorstehend aufgeführten Schritte umfaßt, wodurch die auf einem Bildschirm (410) angezeigten Informationen kontinuierlich in Blindenschrift darstellbar sind.
2. System zur Ausgabe von auf einem Bildschirm angezeigten Informationen in Blindenschrift, zu dem ein Bildschirm (410), ein Wandler (400) zur Umkodierung der auf dem Bildschirm (410) angezeigten Informationen in blindenschriftkodierte Informationen, eine Blindenschriftprägemaschine (300) zum Prägen der von dem Wandler (400) gelieferten blindenschriftkodierten Informationen auf einer Blindenschriftträgerbahn (100), Zuführungsmittel (200, 210, 220) für die kontinuierliche Zuführung der aus einem rückverformbaren Kunststoff gebildeten Blindenschriftträgerbahn (100) zu der Blindenschriftprägemaschine (300), ein hinter der Blindenschriftprägemaschine (300) angeordnetes Ausgabefenster (110), so daß ein Nutzer Zugang zu den Informationen in Blindenschrift auf der Blindenschriftträgerbahn (100) erhält, sowie eine hinter dem Ausgabefenster (110) angeordnete Heizeinrichtung (200) zum Erhitzen mindestens eines Bereichs der geprägten Blindenschriftträgerbahn (100) gehören.
3. System zur Ausgabe von Bildschirminformationen in Blindenschrift nach Anspruch 2, bei dem die Blindenschriftträgerbahn (100) in Form einer Schleife um die Zuführungsmittel (200, 210, 220) geführt wird, zu denen eine Anzahl Rollen einschließlich einer Antriebsrolle (210) gehören.
4. System zur Ausgabe von Bildschirminformationen in Blindenschrift nach Anspruch 3, bei dem die Rol-

len hinter dem Ausgabefenster angeordnet sind und eine Heizrolle (200) als Heizeinrichtung dient.

5. System zur Ausgabe von Bildschirminformationen in Blindenschrift nach Anspruch 2, bei dem die Blindenschriftträgerbahn (100) auf eine zum Abwickeln dienende Zuführungsrolle aufgerollt wird und eine Aufnahmerolle zum Aufwickeln der abgewickelten Bahn vorgesehen ist.

Revendications

1. Procédé d'affichage en braille d'information apparaissant sur un écran à tube à rayons cathodiques CRT (410), qui comprend la conversion de l'information apparaissant sur un écran CRT (410) en information braille, l'impression de l'information braille sur une bande braille (100) en résine à mémoire de forme pour une imprimante braille (300), le transfert de la bande braille en succession vers une fenêtre d'affichage (110), de sorte qu'un utilisateur peut lire l'information braille imprimée, ensuite le chauffage d'au moins une zone imprimée de la bande braille à une température au-dessus de la température de transition du verre de la résine à mémoire de forme, de façon à effacer l'information enregistrée sur la bande braille et à rétablir l'état original, non enregistré, de la bande, et à répéter lesdites étapes ci-dessus, grâce à quoi l'information sur l'écran CRT (410) peut être affichée de façon continue en braille.
2. Appareil d'affichage en braille d'information apparaissant sur un écran CRT, comprenant un affichage CRT (410), un convertisseur (400) pour convertir l'information sur l'écran CRT (410) en une information braille, une imprimante braille (300) pour imprimer l'information en braille du convertisseur (400) sur une bande braille (100), des moyens d'alimentation de bande braille (200,210,220) pour fournir, de façon continue, la bande braille (100) formée à partir d'une résine à mémoire de forme vers l'imprimante braille (300), une fenêtre d'affichage (110) disposée en aval de l'imprimante braille (300), afin de fournir à un utilisateur un accès à l'information braille transcrite sur la bande braille (100), et un dispositif de chauffage (200) situé de plus en aval de la fenêtre d'affichage (110) pour chauffer au moins une zone imprimée de la bande braille (100).
3. Appareil d'affichage en braille selon la revendication 2, dans lequel ladite bande braille (100) est sous la forme d'une boucle s'étendant autour des moyens d'alimentation de bande braille (200,210,220) comprenant une pluralité de rouleaux incluant un rouleau d'entraînement (210).

4. Appareil d'affichage en braille selon la revendication 3, dans lequel l'un desdits rouleaux est situé en aval de ladite fenêtre d'affichage et est un rouleau chauffant (200) servant comme dispositif de chauffage.

5. Appareil d'affichage en braille selon la revendication 2, dans lequel ladite bande braille (100) est enroulée sous la forme d'une bande sans fin qui est disposée sur un rouleau d'alimentation pour le déroulement, et un rouleau d'enroulement est prévu pour rembobiner la bande déroulée.
